

Possible Cure for AIDS

by Walter Woods and Mardi Gieseler

At the Canadian Society of Questor's Conference in 100-Mile House the keynote speaker was a Professor of Geography at the University of Victoria. Dr. Harold Foster gave one of the most astounding lectures we have heard in a long time. He is a medical geographer who looks geographically where diseases occur, or do not occur, and studies the reasons why.

AIDS: A Nutritional Disease

In his research, Dr. Foster noted that AIDS is epidemic in most sub-Saharan African countries except one, Senegal. Why would Senegal have such a low AIDS rate (1-2%) when in all of the surrounding countries it is so high, sometimes in excess of 25+ % of the population? After many years of research, Dr. Foster has evidence that a deficiency of the trace-mineral selenium and three essential amino acids can cause all of the symptoms of AIDS, with or without the HIV virus. In Africa, only Senegal has abundant selenium in the soil and water and adequate nutrition (amino acids).

Although these nutrients are not a cure for HIV infection, research studies found that high doses of selenium and the three essential amino acids (cysteine, glutamine, and tryptophan) given to AIDS patients eliminated most of the AIDS symptoms, sometimes in as little as two or three weeks, and allowing the patient to return to work in as little as one month

Dr. Foster now has ongoing studies in Uganda and Zambia to study the effects of selenium and these three amino acids on large numbers of AIDS patients. Recently Dr. Foster wrote about a double-blind clinical study; "The news from the Ugandan 300 patient trial is very good. Many are recovering rapidly."

(Personal communication, March 2006: 99% of the AIDS patients in the African research trials are responding well to the supplements of selenium and amino acids.)

Why Does HIV Infection Become AIDS?

Selenium and the three amino acids are necessary for the body to produce glutathione peroxidase, which is essential for the human immune system to be healthy, and is also important for many other vital body functions.

Research indicates that the HIV virus needs selenium and the three amino acids in order to replicate. The HIV virus is very good at robbing these vital nutrients from the human body it has infected, leaving the body malnourished. Thus, infection with HIV leaves the human body with a depressed immune system which is unable to fight off the opportunistic diseases which characterize AIDS.

Other Diseases

HIV I and II are not the only viruses that rob these nutrients from the human body. The viruses of Hepatitis A, B, and C, Coxsackie B (thought to be responsible for 1/4 of heart attacks), and other viruses (which encode for a glutathione peroxidase) leave the human body depleted of the necessary nutrients to keep the immune system healthy and functional. Selenium and the three amino acids are also implicated in many cancers, thyroid malfunction, senility, and depression. Some researchers have estimated that as many as 1/3 of the patients in hospitals for depression are simply selenium deficient.

In the 1970's and 80's before many of us had even heard of HIV/AIDS, researchers were studying the relationship of selenium deficiency to cancer. Dr. Foster noted that Senegal, the African country with such high levels of selenium and low rates of HIV/AIDS infection, also has the lowest rate of cancer on earth.

The Disease Belt

In China, there is a large area from the northeast to the southwest that is called the "Disease Belt" where the Hepatitis, Coxsackie B, and AIDS are all on the rise. The Chinese government added selenium supplements to the soils, table salt, and animal feed stocks, and subsequently found a significant reduction in these diseases. For example, in one study of 21,000 people given selenium in their table salt, the hepatitis infection rate dropped more than 50%.

Selenium Bioavailability

We get our necessary amount of selenium from the foods that we eat or from supplementation. Food grown on selenium-deficient soil, and animals fed selenium-deficient food-stocks are contributing to a decrease in selenium in the food chain.

Atmospheric pollution in the rainfall, such as mercury and sulfur, combine with selenium to form insoluble compounds which make selenium unavailable to plants and animals.

In recent years acid rain changed the pH of the soil, decreasing the bioavailability of selenium. Soil acidification lowers the abundance of selenium in the global food chain, which may have contributed to the rapid rise of cancers and HIV/AIDS.

Toxic Levels of Selenium

Many people think that selenium is highly toxic. While an overdose is possible, a healthy person needs about 200 mcg/day; however an HIV infected individual may need 10 times that amount for a while to bring selenium to a healthy level. The first indications of toxicity are garlic breath and yellow finger nails which occur in a sensitive person at about 1000 mcg/day.

We have tried to make a very complicated subject readable for most everyone. We have only touched the tip of the iceberg concerning the health effects of selenium and the three amino acids, as well as, the environmental reasons why selenium is being depleted world wide. If you are interested in more information there are many sources on the Internet.

Dowsing

It is important to dowsing your own nutrition everyday and bring it to optimum for your body. Almost all diseases are nutritionally based either primarily or secondarily. If you wish to know more about see www.lettertorobin.org or Reference: "Health and Nutrition Secrets that can save your life", Russell Blaylock, M.D., Health Press 2006.

More Information

Dr. Foster has a web site where three of his books are available to buy or free to download. Look at www.hdfoster.com for "What Really Causes AIDS," "What Really Causes Alzheimer's," and "What Really Causes Schizophrenia.". He is now working on a book which will probably be out in 2007, "What Really Causes Multiple Sclerosis."
